bednya@theor.jinr.ru

Masses of heavy Standard Model fermions (top-quark, bottom-quark, and tau-lepton) play an important role in the analysis of theories beyond the SM. They serve as low-energy input and reduce the parameter space of such theories. In this paper Minimal supersymmetric extension of the SM is considered and two-loop relations between known SM values of fermion masses and running parameters of the MSSM are studied within the effective theory approach. Both b-quark and τ-lepton have the same quantum numbers with respect to $SU(2)$ group and in the MSSM acquire their masses due to interactions with the same Higgs doublet. As a consequence, for large values of $\tan\beta$ parameter corresponding Yukawa couplings also become large and together with $\tan\beta$ can significantly enhance radiative corrections. In the case of b-quark two-loop $\mathcal{O}(\alpha_s^2)$ contribution to the relation between running bottom-quark mass in QCD and MSSM is known in literature. This paper is devoted to calculation of the NNLO corrections proportional to Yukawa couplings. For the τ-lepton obtained contribution can be considered as a good approximation to the full two-loop result. For the b-quark numerical analysis given in the paper shows that only the sum of strong and Yukawa corrections can play such a role.

1. Introduction

One of the remarkable properties of the supersymmetric (SUSY) extensions of the Standard Model is the possibility to obtain nice unification of gauge couplings at the GUT scale. By means of one-loop renormalization group analysis of the Minimal Supersymmetric Standard Model (MSSM) in the beginning of 90s of the last century the scale of SUSY breaking (TeV) compatible with the unification at 10^{16} GeV was "predicted" [1]. At present modern computer codes (SOFTSUSY [2], SuSpect [3], SPheno [4], ffmssmsc [5]) routinely use two-loop renormalization group equations (RGE) to calculate the spectrum of superparticles given high energy input for SUSY breaking parameters. It is obvious that RGE at higher loops become a system of coupled differential equations so even to study gauge coupling unification one needs to know the value of other, e.g. Yukawa, couplings.

Since for the moment the mass of an elementary particle is the only source of information about its coupling to Higgs boson(s), fermion masses are important low-energy input for all the models beyond the SM.

Top quark, bottom quark and tau-lepton are considered to be the heaviest fermions known in nature. In the context of the MSSM heavy (b and t) quark masses were studied in literature and leading two-loop relations between pole and running masses were found[6,7,8].

The pole mass does not depend on the renormalization scale $\bar{\mu}$ [9,10] so the running masses can in principle be extracted[a] from it at any value of $\bar{\mu}$. However, in practice the scale should be tuned in a proper way to avoid large (high-order) radiative corrections.

At the electroweak scale ($\sim M_Z$) the top-quark pole mass M_t can be used to find the value of the running mass $m_t^{\overline{\rm DR}}$ defined in $\overline{\rm DR}$-renormalization scheme[11,12,13]. This is due to the fact that $M_Z \sim M_t$ and there are no large logarithms in the relation.

The story becomes more involved if one considers b-quark and τ-lepton. In a theory with many different mass scales $m \ll M$ it is not so easy to avoid the appearance of large contributions in the form of $\log M/\bar{\mu}$ and $\log m/\bar{\mu}$ with m, M corresponding to masses of light and heavy particles. This is a "non-decoupling feature" of minimal (MS-like) renormalization schemes [14]. In our case we have $M_b, M_\tau \ll M_Z$ and there are large logarithms in the relations. Moreover, for b-quark there is a renormalon ambiguity[15] that limits the precision of experimental pole mass determination.

In order to solve the problem one usually employ the concept of effective field theory (see, e.g., Ref. 16 for a review) and perform "manual" decoupling of heavy particles. The procedure is well-known in the context of QCD [17] (see also a nice program RunDec[18]).

This approach allows one to relate running parameters in well-established effective theory and corresponding parameters in a more fundamental theory by means of so-called decoupling constants which can be calculated order by order in perturbation theory. In some sense decoupling constants absorb leading contribution of heavy particles to various low-energy quantities. For the b-quark two-loop $\mathcal{O}(\alpha_s^2)$ contribution to the relation between $m_b^{\overline{\rm DR}}$ and $m_b^{\overline{\rm MS}}$ due to strong interactions was obtained within MSSM in Refs. 19, 20. It is known from one-loop[21] and two-loop[8] calculations that strong corrections with virtual supersymmetric particles can be significantly reduced by contributions due to other interactions. In this paper the results for two-loop corrections proportional to Yukawa couplings of heavy SM fermions $\alpha_f = y_f^2/(4\pi)$ with $y_f = \{y_t, y_b, y_\tau\}$ will be presented.

Contrary to the quark masses leptons do not have large uncertainties due to confinement so tau-lepton pole mass can be extracted from the experiment with high precision $M_\tau = 1776.84 \pm 0.17$ MeV (see e.g. Ref. 22).

In principle this fact allows one to determine the value of the running mass (or equivalently Yukawa coupling) very precisely. In the MSSM only one-loop supersymmetric contribution to the relation between pole M_τ and running $m_\tau^{\overline{\rm DR}}$ masses is known[21]. The value of the correction depends on parameters of the MSSM and in some cases can be of the order of 10%.

---

[a] One should keep in mind that we are talking about experimental constraints on running parameters of a model that allows one to reduce the parameter space, expressing, e.g., running masses of fermions in terms of of other parameters (heavy particle masses)

Clearly, in comparison with the experimental uncertainty one-loop contribution is rather big. So it seems to be a good idea to calculate two-loop corrections. Moreover, a general reasoning tells us that the inclusion of the two-loop result allows one to reduce the dependence of the final result on the renormalization (or decoupling) scale $\bar{\mu}$.

Why decoupling constants are important in studying a theory beyond the SM? Together with renormalization group equations (RGE) they allow one to use a power of MS-like schemes in studying high-energy behavior of the MSSM. According to formal perturbation theory in order to obtain the value of, e.g., MSSM b-quark running Yukawa coupling y_b at the GUT scale with L-loop precision one needs to perform a matching of an effective theory (e.g., SM or even Fermi theory) with more fundamental MSSM at $(L-1)$-loop level somewhere at the electroweak (or SUSY) scale[b]. So for one-loop RGE analysis decoupling constants are trivial and running parameters are continuous when one crosses a threshold of some heavy particle. The situation becomes more involved when two- or three-loop RGEs are employed. The parameters obtain a non-zero shift at the scale at which a heavy particle is decoupled. As it was mentioned above many codes use two-loop RGEs and one-loop decoupling corrections are incorporated. It should be pointed out that there exist a dilemma at which scale to decouple heavy particles and how many particles to decouple at chosen scale.

The problem is that when we cross the threshold and decouple a particle we sometimes break a symmetry that guarantees the equality of coupling constants that enter different interaction vertices in a Lagrangian. For example, decoupling of only one squark breaks the supersymmetry which relates the interaction of quarks, gluino and squarks to that of quarks and gluons. As a consequence, one needs to introduce a new coupling constant in the effective theory without the squark. This coupling coincide with the strong coupling constant g_s above the decoupling scale $\mu_{\rm dec}$ but is not equal to g_s below $\mu_{\rm dec}$. Of course, the difference can be calculated. However, when one goes from the MSSM to the SM and decouples every heavy superparticle at its mass a bunch of intermediate effective theories are produced with different symmetries broken (it can also be $SU(2)$ symmetry of the SM) with different RGE equations and different threshold corrections. This way is certainly not the optimal one. In order to make use of all the symmetries presented in full theory during calculation of threshold corrections it seems to be a good idea to match the SM directly to the MSSM ("common scale approach") [23]. So we are left with the issue of choosing the decoupling scale. A common choice is M_Z scale. (see, e.g. Refs. 2,

---

[b] In principle, the result does not depend on the decoupling scale. Again due to truncation of the perturbative series one has to be careful when choosing a particular value.

23). Clearly, at M_Z high order terms can become important. Moreover, there exist some MSSM scenarios[24] when masses of scalar superparticles significantly differ from that of fermion superparticles. In this case high order corrections can also improve the precision of calculation.

In fact, in the context of MSSM RGEs are known up to three loops[25],. The analysis presented in Ref. 25 was based on one-loop threshold (decoupling) corrections and it was mentioned the necessity of two-loop results for self-consistent study. The results presented in this paper together with that obtained earlier[19,26] are aimed to partially fix this mismatch.

The paper organized as follows. First of all, the approximation to the MSSM (so-called gauge-less limit) is described in Section 2. A special attention is paid to the tadpole diagram treatment in Section 3. Then a brief review (see Sec. 4) of decoupling procedure is presented . Section 5 is devoted to the results and numerical analysis of the calculated contribution in a wide range of parameter space of the MSSM. In the end of the paper Conclusions and Acknowledgments can be found.

2. Gauge-less limit of the MSSM

In order to simplify the decoupling procedure as an effective theory I considered a theory of free tau-lepton and five-flavor QCD with massive bottom-quark. Due to smallness of electroweak gauge coupling I neglected them. Moreover, the lightest Higgs boson is assumed to be much heavier then the bottom quark and tau-lepton so it is "left" in the MSSM.

In the effective theory we employ $\overline{\mathrm{MS}}$ minimal renormalization scheme and have the following set of running parameters: mass of the tau-lepton[c] ($m_\tau^{\overline{\mathrm{MS}}}$), mass of the b-quark ($m_b^{\overline{\mathrm{MS}}}$) and strong coupling constant ($g_s^{\overline{\mathrm{MS}}}$). By means of well-known technique [17] they can be related to the parameters of the MSSM defined in so-called $\overline{\mathrm{DR}}$-scheme[d].

In such a simple setup decoupling corrections to the tau-lepton mass coincide with the corrections[e] that enter the relation between the $m_\tau^{\overline{\mathrm{DR}}}$ and the pole mass M_τ. Due to strong interactions for the b-quark we have to take into account the difference between $m_b^{\overline{\mathrm{MS}}}$ and M_b.

Since I neglected electroweak gauge interactions in the effective theory it is convenient to do the same thing in the MSSM. This approximation is called a gauge-less limit of the MSSM[30].

In this limit there is no mixing between gauginos and higgsinos so only the latter have to be taken into account. Both charged and neutral higgsinos have the same mass that is equal to the absolute value of the supersymmetric Higgs mixing parameter μ [f]. The mixing matrices for chargino (U and V) and neutralino (N) are given by the following expressions

---

[c] In the considered approximation "running mass" coincide with the pole mass M_τ.

[d] The issue of $\overline{\mathrm{MS}} \to \overline{\mathrm{DR}}$ transition can be solved be decoupling of unphysical ε-scalars in a way presented in Ref. 19 or by a two-step procedure given in Ref. 26

[e] Actually, with the first term of Large Mass Expansion[27,28,29]

$$U = V = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \qquad N = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & \frac{i}{\sqrt{2}} & \frac{i}{\sqrt{2}} \\ 0 & 0 & -\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{pmatrix} \tag{1}$$

It should be mentioned that in Higgs sector we can have a problem since in the MSSM quartic interaction of Higgs bosons are proportional to the electroweak gauge couplings. Nevertheless, in this paper I assume that there is a successful electroweak symmetry breaking so Higgs bosons have non-trivial vacuum expectation values and treat the gauge-less limit in a formal way.

It is fair to say, that I am not going to be completely self-consistent within the limit. In the next section, Higgs sector of the gauge-less version of MSSM will be discussed together with an issue related to so-called tadpole diagrams. As it will be shown, in our case we have a very degenerate situation in Higgs sector with four massless bosons and four bosons with equal masses. Clearly, this is not satisfactory from the phenomenological point of view.

3. Higgs sector and tadpoles

In the MSSM like in the SM the electroweak symmetry is broken by a vacuum state, which can be characterized by the vacuum expectation values v_1 and v_2 of two Higgs doublets H_1 and H_2

$$H_1 = \frac{1}{\sqrt{2}} \begin{pmatrix} v_1 + \phi_1 - i\chi_1 \\ -\sqrt{2}\phi_1^- \end{pmatrix}, \quad H_2 = \frac{1}{\sqrt{2}} \begin{pmatrix} \sqrt{2}\phi_2^+ \\ v_2 + \phi_2 + i\chi_2 \end{pmatrix}. \tag{2}$$

In the true vacuum the first derivative of the effective potential (tadpole) should vanish. However, naive calculation of one-loop tadpoles for neutral $\mathcal{CP}$-even Higgs bosons h and H shows that they do not vanish. This can be interpreted in the following way. The vacuum expectation values for the Higgs bosons that we substituted in the tree-level Higgs potential minimize the tree-level potential instead of effective one.

In order to deal with the problem I adopt the reasoning of Refs. 6, 21. Tree-level tadpoles for ϕ_1 and ϕ_2 that appear in the MSSM Lagrangian after substitution of (2) look like

$$\begin{aligned} T_1 &= \frac{g^2 + g'^2}{8}(v_1^2 - v_2^2)v_1 + m_1^2 v_1 - m_3^2 v_2, \\ T_2 &= \frac{g^2 + g'^2}{8}(v_2^2 - v_1^2)v_2 + m_2^2 v_2 - m_3^2 v_1, \end{aligned} \tag{3}$$

---

[f] In this work I assumed that $\mu > 0$ which corresponds the positive contribution to the muon anomalous magnetic moment.

where g, g' are gauge $SU(2) \times U(1)$ couplings (they will be neglected in what follows) and m_1^2, m_2^2, and m_3^2 are soft supersymmetry breaking parameters of the Higgs potential[6]. Both T_1 and T_2 are assumed to be non-zero and serve as counter-terms to cancel loop-induced tadpoles. As a consequence, I do not need to consider diagrams with tadpole insertions like in Refs. 31, 32, 33 since they are precisely canceled by the tree-level counter-term. However, they do not disappear completely and manifest themselves in the mass matrices of all Higgs bosons. In the gauge-less limit mass matrices have the following form ($\Phi = \{\phi_i, \phi_i^\pm, \xi_i\}$, $i = 1, 2$)

$$M_\Phi = \begin{pmatrix} m_1^2 & -m_3^2 \\ -m_3^2 & m_2^2 \end{pmatrix} = m_3^2 \begin{pmatrix} \cot\beta & -1 \\ -1 & \tan\beta \end{pmatrix} + \delta M_\Phi \tag{4}$$

$$\delta M_\Phi = \begin{pmatrix} \frac{T_1}{v_1} & 0 \\ 0 & \frac{T_2}{v_2} \end{pmatrix} \tag{5}$$

Since T_1 and T_2 should cancel loop-induced tadpoles they are at least $\mathcal{O}(g^2)$ with g being some coupling constant of the theory. Consequently, in order to obtain tree-level mass matrices one should set $T_1 = T_2 = 0$ and diagonalize only first term in (4). Clearly, this matrix has two eigenvalues $(0, m_3^2)$ and it is diagonalized by the rotation with angle β.

As it was mentioned in the end of the previous section this is not a satisfactory result. I decided to be slightly more close to the MSSM and introduce different masses for all physical Higgs bosons together with a different mixing angle α for $\mathcal{CP}$-even states

$$\begin{pmatrix} H \\ h \end{pmatrix} = R(\alpha) \begin{pmatrix} \phi_1^0 \\ \phi_2^0 \end{pmatrix}, \qquad R(\theta) = \begin{pmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{pmatrix}. \tag{6}$$

$$\begin{pmatrix} G_0 \\ A \end{pmatrix} = R(\beta) \begin{pmatrix} \chi_1^0 \\ \chi_2^0 \end{pmatrix}, \tag{7}$$

$$\begin{pmatrix} G^+ \\ H^+ \end{pmatrix} = R(\beta) \begin{pmatrix} \phi_1^+ \\ \phi_2^+ \end{pmatrix}. \tag{8}$$

After tree-level diagonalization linear and quadratic parts of the Higgs potential can be rewritten in the following way:

$$\begin{aligned} V_2 &= T_H\, H + T_h\, h + \frac{1}{2}\left(M_H^2\, H^2 + M_h^2\, h^2 + M_A^2\, A^2\right) + M_{H^\pm}^2 H^+ H^- \\ &+ (H\ h) \begin{pmatrix} b_{HH} & b_{hH} \\ b_{hH} & b_{hh} \end{pmatrix} \begin{pmatrix} H \\ h \end{pmatrix} + (G^0\ A) \begin{pmatrix} b_{G^0G^0} & b_{G^0A} \\ b_{G^0A} & b_{AA} \end{pmatrix} \begin{pmatrix} G^0 \\ A \end{pmatrix} \\ &+ (G^+\ H^+) \begin{pmatrix} b_{G^+G^-} & b_{G^+H^-} \\ b_{G^+H^-} & b_{H^+H^-} \end{pmatrix} \begin{pmatrix} G^- \\ H^- \end{pmatrix}. \end{aligned} \tag{9}$$

Here H, h are neutral $\mathcal{CP}$-even Higgs bosons, A and G^0 — neutral $\mathcal{CP}$-odd higgs and Goldstone boson correspondingly, $H^\pm$ and $G^\pm$ — charged higgs and goldstone bosons. Additional contributions to mass matrices come from δM_Φ (see Eq. (5))

and can be expressed in terms of rotated tadpoles $T_H,\ T_h$

$$\begin{pmatrix} T_H \\ T_h \end{pmatrix} = R(\alpha) \begin{pmatrix} T_1 \\ T_2 \end{pmatrix}, \tag{10}$$

a vacuum expectation value $v = \sqrt{v_1^2 + v_2^2}$, and Higgs mixing angles β, α [6]

$$b_{HH} = \frac{2}{v\, s_{2\beta}} \left(T_H (c_\alpha^3\, s_\beta + s_\alpha^3 c_\beta)\ + T_h s_\alpha c_\alpha s_{\alpha-\beta} \right), \tag{11a}$$

$$b_{Hh} = \frac{s_{2\alpha}}{v\, s_{2\beta}} \left(T_H s_{\alpha-\beta} + T_h c_{\alpha-\beta} \right), \tag{11b}$$

$$b_{hh} = \frac{2}{v\, s_{2\beta}} \left(T_H c_\alpha s_\alpha c_{\alpha-\beta}\ + T_h (c_\alpha^3 c_\beta - s_\alpha^3 s_\beta) \right), \tag{11c}$$

$$b_{G^0G^0} = b_{G^+G^-} = \frac{1}{v} \left(T_H c_{\alpha-\beta} - T_h s_{\alpha-\beta} \right), \tag{11d}$$

$$b_{G^0A} = b_{G^+H^-} = \frac{1}{v} \left(T_H s_{\alpha-\beta} + T_h c_{\alpha-\beta} \right), \tag{11e}$$

$$b_{AA} = b_{H^+H^-} = \frac{2}{v\, s_{2\beta}} \left(T_H (s_\beta^3 c_\alpha + c_\beta^3 s_\alpha) + T_h (c_\beta^3 c_\alpha - s_\beta^3 s_\alpha) \right), \tag{11f}$$

where $c_\theta = \cos\theta$ and $s_\theta = \sin\theta$ for some angle θ. Since the contribution due tadpoles does not depend on external momenta it can be taken into account by introduction of additional non-minimal counter-terms for higgs masses and mixing.

In the end of this section I would like to mention another issue related to Goldstone bosons. In the gauge-less limit there are no gauge bosons to "eat" goldstones so the latter are massless and the global $SU(2) \times U(1)$ symmetry prevents them to acquire mass. However, in perturbation theory it is not so obvious. For example, if one does not take into account the contributions (11) during calculation of goldstone boson self-energies $\Sigma_{GG}(p^2)$ non-zero masses for G^0 and $G^\pm$ are immediately generated since $\Sigma_{GG}(0) \neq 0$. It worth mentioning that we also run into a problem with spurious infra-red (IR) divergences when we try to calculate Feynman integrals with $\Sigma_{GG}(p)$ insertions. The role of tadpoles is crucial here since they precisely cancel this non-zero contribution keeping Goldstone bosons massless.

In deriving the result presented here I was using non-zero masses for Goldstone bosons denoted by $M_{G_0}^2$ and $M_{G^\pm}^2$ which allows me not to deal with mentioned IR problem explicitly. This can be justified since in the full MSSM when linear R_ξ-gauge is employed Goldstone boson masses are proportional to that of corresponding gauge bosons. This introduces gauge dependence in the result. However, numerical analysis shows that the dependence is negligible if one takes into account tadpole contribution.

4. Decoupling procedure

The process of obtaining decoupling corrections for b-quark mass is described in great details in Ref. 19. I closely follow the same procedure. Here I would like to stress some of important steps of the calculation.

In order to obtain a final result for the relation between running masses in the MSSM and our effective theory we need to know so-called "bare" decoupling-constants $\zeta_{m_f,B}$ up to two-loop level. These constants relate bare parameters in the effective five-flavor QCD (underlined parameters) to that of the MSSM

$$\underline{m_{f,B}} = \zeta_{m_f,B}(\alpha_B, M_B) \times m_{f,B}, \qquad f = \{b, \tau\} \tag{12}$$

and depend on bare coupling constants $\alpha_B = \{\alpha_s, \alpha_t, \alpha_b, \alpha_\tau\}_B$ and on bare masses of heavy particles denoted collectively by M_B.

The needed relations can be derived from (12) by proper renormalization of the left- and right-hand sides. Since $\underline{m_f(\bar{\mu})} \equiv m_f^{\overline{\rm MS}}(\bar{\mu})$ and $m_f(\bar{\mu}) \equiv m_f^{\overline{\rm DR}}(\bar{\mu})$ are defined in different theories we have

$$\begin{aligned} \underline{m_{f,B}} &= Z_{m_f}^{\overline{\rm MS}}\left(\alpha^{\overline{\rm MS}}\right) \times m_f^{\overline{\rm MS}}, \qquad && \alpha^{\overline{\rm MS}} = \alpha_s^{\overline{\rm MS}} \\ m_{f,B} &= Z_{m_f}^{\overline{\rm DR}}\left(\alpha^{\overline{\rm DR}}\right) \times m_f^{\overline{\rm DR}} \qquad && \alpha^{\overline{\rm DR}} = \{\alpha_s, \alpha_t, \alpha_b, \alpha_\tau\}^{\overline{\rm DR}}. \end{aligned} \tag{13}$$

As a consequence an implicit equation

$$m_f^{\overline{\rm MS}} = m_f^{\overline{\rm DR}} \times \frac{Z_{m_f}^{\overline{\rm DR}}(\alpha^{\overline{\rm DR}})}{Z_{m_f}^{\overline{\rm MS}}(\alpha^{\overline{\rm MS}})} \times \zeta_{m_f,B}\left(Z_\alpha^{\overline{\rm DR}}\alpha^{\overline{\rm DR}}, Z_M^{\overline{\rm DR}} M^{\overline{\rm DR}}\right) \tag{14}$$

can be solved in perturbation theory by expressing $\alpha^{\overline{\rm MS}}$ in terms of $\alpha^{\overline{\rm DR}}$ and expanding the result in $\alpha^{\overline{\rm DR}}$.

Simple power counting tells us that in our case we need to know $Z_\alpha^{\overline{\rm DR}}$ and $Z_M^{\overline{\rm DR}}$ up to one-loop level and both Z_{m_f}'s – up to two loops. Renormalization constants for the MSSM parameters $Z_\alpha^{\overline{\rm DR}}$ and $Z_M^{\overline{\rm DR}}$ can be found in Appendix A. The expressions for $Z_{m_f}^{\overline{\rm DR}}$ that were used in my calculation looks like

$$\begin{aligned} Z_{m_b}^{\overline{\rm DR}} = 1 &- \frac{\alpha_s}{4\pi}\left(\frac{2C_F}{\varepsilon}\right) + \frac{\alpha_b}{4\pi}\frac{3}{2\varepsilon} + \frac{\alpha_t}{4\pi}\frac{1}{2\varepsilon} \\ &- \frac{\alpha_s\alpha_b}{(4\pi)^2}\left(\frac{6C_F}{\varepsilon^2}\right) - \frac{\alpha_s\alpha_t}{(4\pi)^2}\left(\frac{2C_F}{\varepsilon^2}\right) + \frac{\alpha_t\alpha_b}{(4\pi)^2}\left(\frac{7}{4\varepsilon^2} - \frac{1}{2\varepsilon}\right) \\ &+ \frac{\alpha_t^2}{(4\pi)^2}\left(\frac{13}{8\varepsilon^2} - \frac{5}{4\varepsilon}\right) + \frac{\alpha_b^2}{(4\pi)^2}\left(\frac{45}{8\varepsilon^2} - \frac{13}{4\varepsilon}\right) + \frac{\alpha_b\alpha_\tau}{(4\pi)^2}\left(\frac{3}{4\varepsilon^2} - \frac{3}{4\varepsilon}\right) \\ &+ \frac{\alpha_s^2}{(4\pi)^2}C_F\left((2C_F + 3C_A - 6)\frac{1}{\varepsilon^2} + (2C_F - 3C_A + 6)\frac{1}{\varepsilon}\right), \end{aligned} \tag{15}$$

$$Z_{m_\tau}^{\overline{\rm DR}} = 1 + \frac{\alpha_\tau}{4\pi}\frac{3}{2\varepsilon} + \frac{\alpha_\tau^2}{(4\pi)^2}\left(\frac{33}{8\varepsilon^2} - \frac{7}{4\varepsilon}\right) + \frac{\alpha_\tau\alpha_b}{(4\pi)^2}\left(\frac{9}{4\varepsilon^2} - \frac{9}{4\varepsilon}\right) \tag{16}$$

with $C_F = 4/3$ and $C_A = 3$ being quadratic casimirs of $SU(3)$ group. The renormalization constants can be easily obtained, e.g., from the formula $m_f = y_f v_1/\sqrt{2}$ ($f = b, \tau$) and well-known RGEs for Yukawa couplings y_b, y_τ, and vacuum expectation value v_1 (see Refs. 34, 35).

Corresponding expressions for $Z_{m_b}^{\overline{\rm MS}}$ defined in five-flavor QCD can be found in Refs. 9, 36. As it was mentioned earlier $Z_{m_\tau}^{\overline{\rm MS}} = 1$ in our approximation.

Since there is $\alpha_s^{\overline{\rm MS}}$ in the right-hand side of (14) we also need one-loop relation-between $\alpha_s^{\overline{\rm MS}}$ and $\alpha_s^{\overline{\rm DR}}$. This relation together with the expressions for full MSSM one-loop threshold corrections can be found in Appendix D of Ref. 21. In order to derive needed $\mathcal{O}(\alpha_f)$ contribution to the fermion mass decoupling constants self-energies presented in this reference have to be expanded in external momenta and masses of the considered fermion and the mixing (1) has to be taken into account.

We are left with the only missing piece of the formula (14), i.e., two-loop contribution $\delta\zeta_{m_f}^{(2)}$ to ζ_{m_f}. Corrections of the order $\mathcal{O}(\alpha_s^2)$ were found in Refs. 19, 20. The contribution proportional to Yukawa couplings of heavy SM fermions is obtained in this paper by means of a FORM[37] program specially written for calculation of decoupling constants in the MSSM. Corresponding diagrams were generated with the help of FeynArts[38,39].

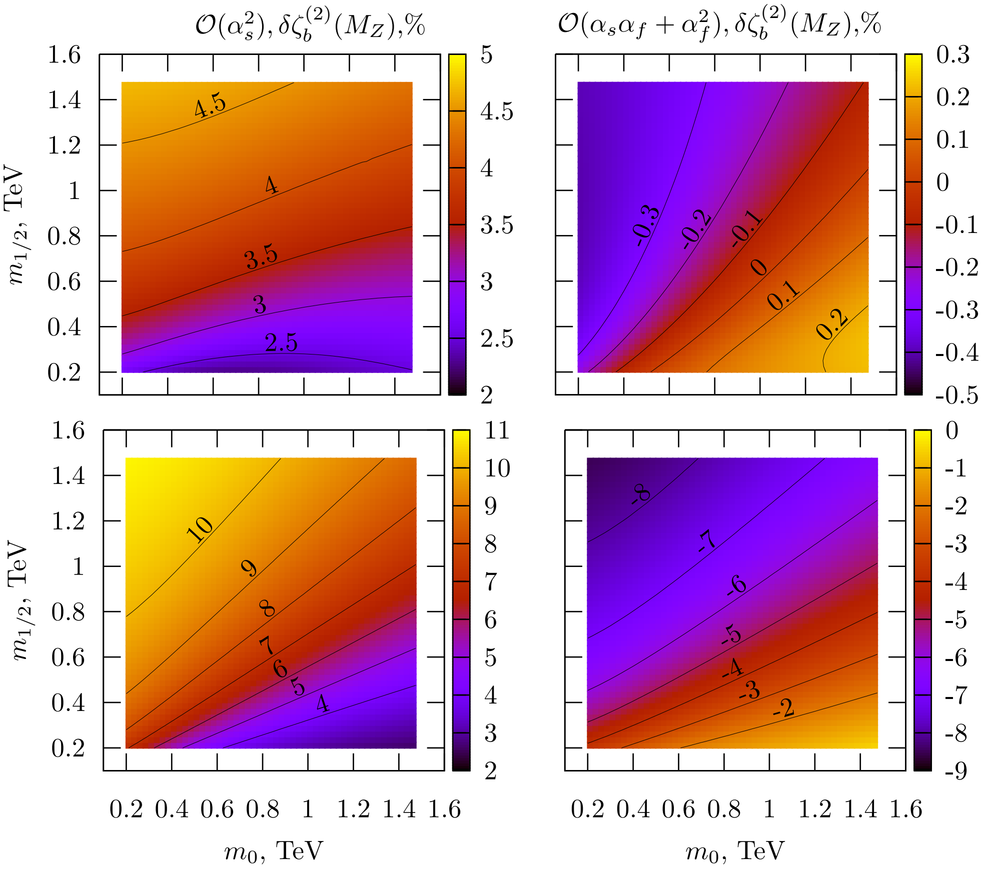

Fig. 1. Two-loop $\mathcal{O}(\alpha_s^2)$ and $\mathcal{O}(\alpha_s\alpha_f + \alpha_f^2)$ contributions to $\delta\zeta_{m_b}^{(2)}$ as functions of m_0 and $m_{1/2}$ for $A_0 = 0$. Upper row is for $\tan\beta = 10$ and the lower one is for $\tan\beta = 50$.

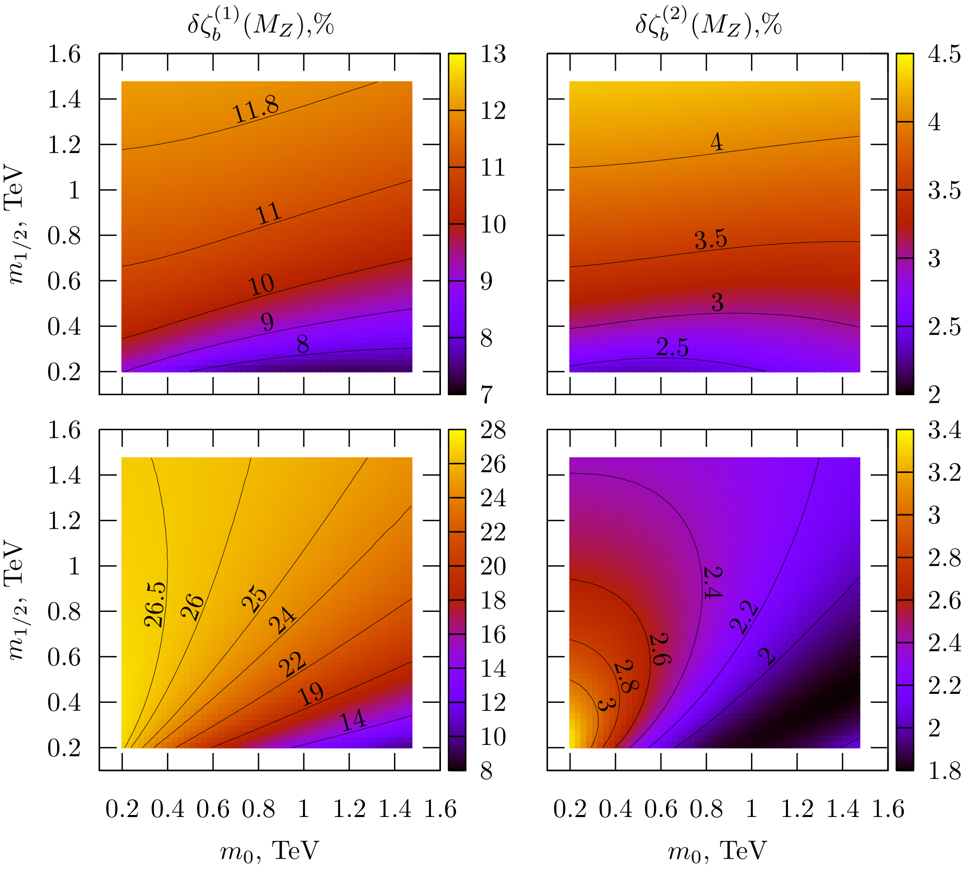

Fig. 2. Comparison of one- and two-loop contribution to the decoupling constant for the b-quark running mass ζ_{m_b} as functions of m_0 and $m_{1/2}$ for $A_0 = 0$. Upper row is for $\tan\beta = 10$ and the lower one is for $\tan\beta = 50$.

5. Results

In this section I present the numerical analysis of the obtained result. Analytical expressions are huge and have been stored in the form of Mathematica code and GiNaC [40] archive format[g]. The former allows to obtain numerical value for $\delta\zeta^{(2)}_{m_b}$ and $\delta\zeta^{(2)}_{m_\tau}$ given the *running parameters* of the MSSM. The latter gives us an opportunity to include the calculated corrections in the SoftSusy program [2] to evaluate them and to see the influence of the two-loop thresholds on the resulting spectrum and running parameters. In SoftSusy matching performed at the electroweak scale so for numerical results it is assumed that decoupling scale $\mu_{\text{dec}} = M_Z$.

In Fig. 1 one can find typical dependence of different two-loop contributions to the decoupling constant $\delta\zeta^{(2)}_{m_b}$ of the b-quark mass on Constrained MSSM parameters

---

[g] Both the expressions are available from the author by demand.

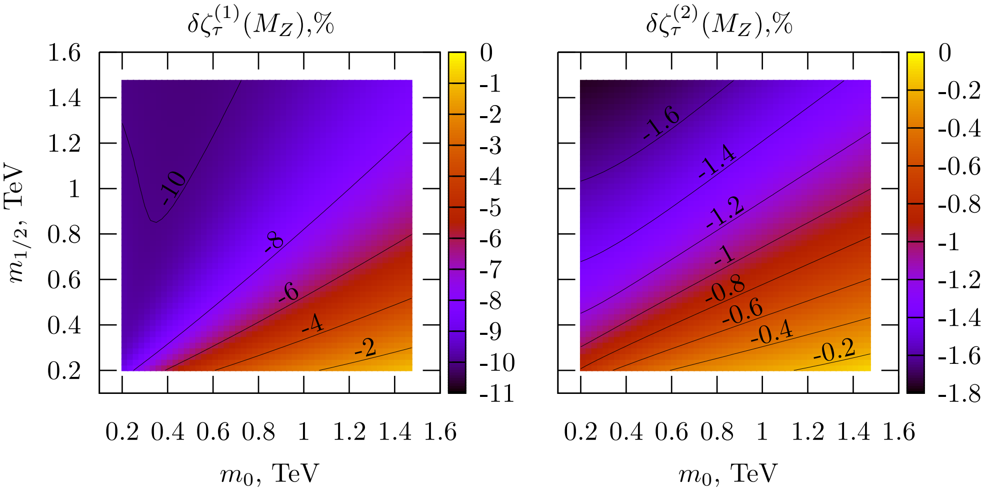

Fig. 3. Comparison of one- and two-loop contribution to τ-lepton mass decoupling constant ζ_{m_τ} as functions of m_0 and $m_{1/2}$ for $A_0 = 0$ and $\tan\beta = 50$.

m_0 and $m_{1/2}$ for fixed value of $A_0 = 0$ and for $\tan\beta = 10$ (upper row) and $\tan\beta = 50$ (lower row).

As one can see corrections due to Yukawa interactions tend to compensate $\mathcal{O}(\alpha_s^2)$ contribution. The effect of $\mathcal{O}(\alpha_s\alpha_f + \alpha_f^2)$ increases with $\tan\beta$. The comparison of first column of Fig. 1 and the resulting two-loop corrections presented in Fig. 2) shows us that for large $\tan\beta = 50$ total $\delta\zeta_{m_b}^{(2)}$ varies in the range of 2 - 4 % while $\mathcal{O}(\alpha_s^2)$ contribution varies in considerable wider range 2-11 %. From this fact one can immediately deduce the importance of two-loop Yukawa decoupling corrections for b-quark running mass in the region of large $\tan\beta$.

The sum of the above contributions is compared with full one-loop MSSM decoupling constants in Fig. 2. It is easy to see that the resulting two-loop correction both for large and low values of $\tan\beta$ lies in the region of few percents and does not exceed the relative uncertainty of the input parameter $\bar{m}_b \equiv m_b^{\overline{\text{MS}}}(m_b^{\overline{\text{MS}}}) = 4.20 \pm 0.18$ GeV [22].

In some sense it is a bad news since we obtained the result that is negligible. Nevertheless, one can be sure that large one-loop threshold corrections for b-quark running mass widely discussed in literature (see, e.g., Ref. 41) are indeed reliably approximate the full result.

For tau-lepton strong interactions do not contribute to the mass decoupling constant at two-loop level so the corrections are relatively small in this case. Typical value of two-loop corrections $\mathcal{O}(\alpha_\tau^2 + \alpha_\tau\alpha_q)$ with $q = t, b$ for low values of $\tan\beta$ is 10^{-3} % which is small even with respect to relative experimental error of the pole mass M_τ (10^{-2} %). With the increase of $\tan\beta$ considered contribution is enhanced and can reach the value of few percents (see Fig. 3)

In the end of this section I would like to demonstrate the role of tadpole contribu-

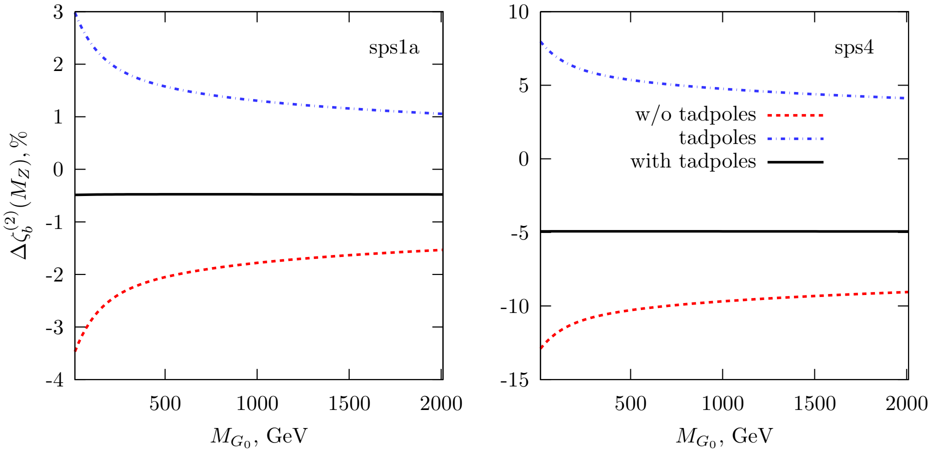

Fig. 4. The dependence of two-loop $\mathcal{O}(\alpha_s\alpha_f + \alpha_f^2)$ correction to $\delta\zeta_{m_b}^{(2)}$ on Goldstone boson mass $M_{G_0}^2$ for SPS1a ($m_0 = 100$ GeV , $m_{1/2} = 250$ GeV , $A_0 = -100$ GeV , $\tan\beta = 10$) and SPS4 ($m_0 = 400$ GeV , $m_{1/2} = 300$ GeV , $A_0 = 0$, and $\tan\beta = 50$) scenarios. Contribution due to tadpoles (dot-dashed line) almost completely cancel (dashed-line) naively calculated correction without tadpoles.

tion discussed in Sec. 3. Figure 4 shows the dependence of $\mathcal{O}(\alpha_s\alpha_f + \alpha_f^2)$ contribution to $\delta\zeta_{m_b}^{(2)}$ on Goldstone boson mass $M_{G_0}^2$ for SPS1 and SPS4 scenarios [42]. One can see that if we neglect tadpole contribution we overestimate the value of the correction and introduce significant dependence on $M_{G_0}^2$ which can be interpreted as a gauge dependence.

6. Conclusions

The biggest experimental facility in the world, Large Hadron Collider [43], has already been built and we are waiting for first physical run of the machine. We hope that there will be something that allow us to solve at least some of the problems of the SM and we believe that it will be supersymmetry.

The MSSM is a viable candidate for a theory beyond the SM. It has a lot of parameters most of which related to supersymmetry breaking and they have to be determined from future experiments. However, other parameters are already constrained from known low-energy input. Both bottom-quark and tau-lepton masses are among them.

In this paper the relations between corresponding running masses $m_b^{\overline{\mathrm{DR}}}$ and $m_\tau^{\overline{\mathrm{DR}}}$ defined in the MSSM and known low-energy experimental input ($\bar{m}_b$ and M_τ) were considered. Two-loop (decoupling) corrections to this relations proportional to Yukawa couplings of heavy SM fermions were calculated.

For the b-quark it was found that $\mathcal{O}(\alpha_s\alpha_f + \alpha_f^2)$ corrections are important for large $\tan\beta$ and significantly reduce two-loop strong contribution calculated earlier [19,20]. From Figure 1 one can see that mentioned contributions usually have different signs. With the increase of $m_{1/2}$ (m_0) absolute value of the corrections increases (decreases). Due to this kind of behavior they tend to compensate each other in the whole region of considered $m_0 - m_{1/2}$ plane lowering the sum below current uncertainty in the input parameter $\bar{m}_b$.

Two-loop threshold corrections to τ-lepton mass that were obtained in this paper turns out to be negligible in the region of low $\tan\beta$. With the increase of $\tan\beta$ they can reach the value of few percents and exceed the experimental error of M_τ .

From the presented analysis it is obvious that the two-loop decoupling corrections are too small and can not significantly modify MSSM spectrum produced by public computer codes. Variations in the spectrum due to calculated corrections are comparable with variations due to uncertainties in the low-energy input parameters.

Nevertheless, obtained result allows us to be sure that, e.g. for large $\tan\beta$ one-loop approximation is good enough. Moreover, if some new physics is established at LHC we will be ready to perform precision tests of SUSY models and their GUT extensions with the help of three-loop RGEs.

7. Acknowledgments

I would like to thank A. Sheplyakov for fruitful discussions and for his computer code [44] that allows me to use GiNaC in numerical analysis. Financial support from RFBR grant No. 08-02-00856 and from a Grant for Young Scientist of JINR is kindly acknowledged.

Appendix A. Renormalization constants

To obtain finite result for threshold corrections we need to rewrite bare decoupling constants (14) in terms of renormalized parameters of the MSSM. I collected all the needed counter-terms in this Appendix. In what follows the following notations are used: $m_{\tilde{g}}$ corresponds to gluino mass, A_f with $f = \{t, b, \tau\}$ — soft trilinear couplings, $X_t = A_t - \mu\cot\beta$, and $X_f = A_f - \mu\tan\beta$ with $f = \{b, \tau\}$ are off-diagonal elements of sfermion mixing matrices. Sfermion masses are denoted by $m^2_{\tilde{f}_{1,2}}$ and $m^2_{\tilde{\nu}}$ (sneutrino). For sines and cosines of sfermion θ_f mixing angles abbreviations $s_f \equiv \sin\theta_f$ and $s_{nf} \equiv \sin(n\theta_f)$ $(n = 2, 4)$, etc are used.

For bare scalar mass m^2_B, bare fermion mass M_B, bare coupling constant α_B, and some bare mixing angle θ_B corresponding counter-terms δm^2, δZ_M, δZ_α, and $\delta\theta$ are defined by $m^2_B = m^2 + \delta m^2$, $M_B = (1 + \delta Z_M)M$, $\alpha_B = \alpha(1 + \delta Z_\alpha)$, and $\theta_B = \theta + \delta\theta$ with m^2, M, α, and θ being running parameters in $\overline{\mathrm{DR}}$ scheme.

\end{aligned}
\tag{A.3}
$$

The counter-terms satisfy the following relation

$$
\begin{aligned}
\delta M^2_{\tilde{Q}} &= \delta m^2_{\tilde{b}_1} c_b^2 + \delta m^2_{\tilde{b}_2} s_b^2 + (m^2_{\tilde{b}_2} - m^2_{\tilde{b}_1}) s_{2b} \delta\theta_b - 2 m_b \delta m_b \\
&= \delta m^2_{\tilde{t}_1} c_t^2 + \delta m^2_{\tilde{t}_2} s_t^2 + (m^2_{\tilde{t}_2} - m^2_{\tilde{t}_1}) s_{2t} \delta\theta_t - 2 m_t \delta m_t,
\end{aligned}
\tag{A.4}
$$

which is a consequence of $SU(2)$-invariance of the MSSM Lagrangian. By means of

$$\begin{aligned} s_{2b} &= \frac{2m_b X_b}{m^2_{\tilde{b}_1} - m^2_{\tilde{b}_2}} \\ c_{2b} &= \frac{M^2_{\tilde{Q}} - M^2_{\tilde{b}}}{m^2_{\tilde{b}_1} - m^2_{\tilde{b}_2}} \end{aligned} \tag{A.5}$$

it is easy to convince oneself that (A.1) (A.2) and (A.3) can be rewritten in the following way

$$\begin{aligned} (4\pi)\delta m^2_{\tilde{b}_{1,2}} = \frac{1}{2}\Bigg[& \delta M^2_{\tilde{Q}} + \delta M^2_{\tilde{b}} \pm \frac{M^2_{\tilde{Q}} - M^2_{\tilde{b}}}{m^2_{\tilde{b}_1} - m^2_{\tilde{b}_2}} \left(\delta M^2_{\tilde{Q}} - \delta M^2_{\tilde{b}}\right) \\ & + 4m_b^2 \frac{\delta m_b}{m_b} \pm \frac{2m_b X_b}{m^2_{\tilde{b}_1} - m^2_{\tilde{b}_2}} \left(\delta m_b X_b + m_b \delta X_b\right)\Bigg] \end{aligned} \tag{A.6}$$

$$(4\pi)\delta\theta_b = \frac{m_b X_b}{\left(m^2_{\tilde{b}_1} - m^2_{\tilde{b}_2}\right)^2}\left[\left(\frac{\delta m_b}{m_b} + \frac{\delta X_b}{X_b}\right)\left(M^2_{\tilde{Q}} - M^2_{\tilde{b}}\right) - \left(\delta M^2_{\tilde{Q}} - \delta M^2_{\tilde{b}}\right)\right], \tag{A.7}$$

where[h]

$$\frac{\delta m_b}{m_b} = \frac{3}{2}\frac{\alpha_b}{\varepsilon} + \frac{1}{2}\frac{\alpha_t}{\varepsilon} - 2C_F\frac{\alpha_s}{\varepsilon}, \tag{A.8}$$

$$\frac{\delta X_b}{X_b} = \frac{1}{X_b}\left(\delta A_b - \delta\mu \tan\beta - \mu\delta\tan\beta\right) \tag{A.9}$$

$$= 3\frac{\alpha_b}{\varepsilon} + \frac{1}{X_b}\left(3A_b\frac{\alpha_b}{\varepsilon} + A_t\frac{\alpha_t}{\varepsilon} + X_\tau\frac{\alpha_\tau}{\varepsilon} + 4C_F\frac{\alpha_s}{\varepsilon}m_{\tilde{g}}\right), \tag{A.10}$$

$$\frac{\delta\mu}{\mu} = \frac{3}{2}\frac{\alpha_b + \alpha_t}{\varepsilon} + \frac{1}{2}\frac{\alpha_\tau}{\varepsilon}, \tag{A.11}$$

$$\frac{\delta\tan\beta}{\tan\beta} = -\frac{3}{2}\frac{\alpha_t}{\varepsilon} + \frac{3}{2}\frac{\alpha_b}{\varepsilon} + \frac{1}{2}\frac{\alpha_\tau}{\varepsilon}, \tag{A.12}$$

$$\delta A_b = 4C_F\frac{\alpha_s}{\varepsilon}m_{\tilde{g}} + 6A_b\frac{\alpha_b}{\varepsilon} + A_t\frac{\alpha_t}{\varepsilon} + A_\tau\frac{\alpha_\tau}{\varepsilon}, \tag{A.13}$$

$$\begin{aligned} \delta M^2_{\tilde{Q}} = & -4C_F\frac{\alpha_s}{\varepsilon}m^2_{\tilde{g}} + \frac{\alpha_b}{\varepsilon}\left(M^2_{\tilde{Q}} + M^2_{\tilde{t}} + m^2_{H_1} + A_t^2\right) \\ & + \frac{\alpha_t}{\varepsilon}\left(M^2_{\tilde{Q}} + M^2_{\tilde{b}} + m^2_{H_2} + A_b^2\right), \end{aligned} \tag{A.14}$$

$$\delta M^2_{\tilde{b}} = -4C_F\frac{\alpha_s}{\varepsilon}m^2_{\tilde{g}} + 2\frac{\alpha_b}{\varepsilon}\left(M^2_{\tilde{Q}} + M^2_{\tilde{t}} + m^2_{H_1} + A_t^2\right), \tag{A.15}$$

Renormalization constants for top-squark masses and mixing can be obtained from the expressions above by substitution $b \leftrightarrow t$, $c_\beta \leftrightarrow s_\beta$, $c_\alpha \leftrightarrow s_\alpha$ and $\alpha_\tau \rightarrow 0$

[h] needed counter-terms can be extracted from corresponding beta-functions given, e.g., in Ref. 45

Appendix A.2. *Scalar leptons*

$$(4\pi)\delta m^2_{\tilde\nu} = \frac{\alpha_\tau}{\varepsilon}\left(A^2_\tau - \mu^2 + m^2_{\tilde\tau_1}s^2_\tau + m^2_{\tilde\tau_2}c^2_\tau + m^2_{\tilde\nu} - m^2_\tau + c^2_\beta M^2_{G^\pm} + s^2_\beta M^2_{H^\pm}\right) \tag{A.16}$$

$$\begin{aligned}(4\pi)\,\delta m^2_{\tilde\tau_1} &= \frac{\alpha_\tau}{\varepsilon}s^2_\tau\left(A^2_\tau - \mu^2 + m^2_{\tilde\tau_1} + m^2_{\tilde\nu} + M^2_{G^\pm}c^2_\beta + M^2_{H^\pm}s^2_\beta\right) + \frac{\alpha_b}{\varepsilon}3X_b m_\tau s_{2\tau}\\ &+ \frac{\alpha_\tau}{\varepsilon}\left(A^2_\tau - \mu^2 + \frac{1}{2}\left(M^2_A s^2_\beta + M^2_{G_0}c^2_\beta + M^2_h s^2_\alpha + M^2_H c^2_\alpha\right)\right)\\ &+ \frac{\alpha_\tau}{\varepsilon}\left(m^2_{\tilde\tau_1}(1+s^2_{2\tau}) + m^2_{\tilde\tau_2}(1-s^2_{2\tau}) + 3s_{2\tau}A_\tau m_\tau + m^2_\tau c^2_\tau\right)\end{aligned} \tag{A.17}$$

$$\begin{aligned}(4\pi)\,\delta m^2_{\tilde\tau_2} &= \frac{\alpha_\tau}{\varepsilon}c^2_\tau\left(A^2_\tau - \mu^2 + m^2_{\tilde\tau_2} + m^2_{\tilde\nu} + M^2_{G^\pm}s^2_\beta + M^2_{H^\pm}c^2_\beta\right) - \frac{\alpha_\tau}{\varepsilon}3X_b m_\tau s_{2\tau}\\ &+ \frac{\alpha_\tau}{\varepsilon}\left(A^2_\tau - \mu^2 + \frac{1}{2}\left(M^2_A s^2_\beta + M^2_{G_0}c^2_\beta + M^2_h s^2_\alpha + M^2_H c^2_\alpha\right)\right)\\ &+ \frac{\alpha_\tau}{\varepsilon}\left(m^2_{\tilde\tau_1}(1-s^2_{2\tau}) + m^2_{\tilde\tau_2}(1+s^2_{2\tau}) - 3s_{2\tau}A_\tau m_\tau + m^2_\tau s^2_\tau\right)\end{aligned} \tag{A.18}$$

$$\begin{aligned}(4\pi)\,\delta\theta_\tau &= \Bigg[3\frac{\alpha_b}{\varepsilon}m_\tau X_b c_{2l} + \frac{s_{2\tau}}{4}\frac{\alpha_\tau}{\varepsilon}\left(m^2_{\tilde\tau_1} + m^2_{\tilde\tau_2} - 2m^2_\tau\right)\\ &+ \frac{\alpha_\tau}{\varepsilon}\frac{s_{2\tau}}{2}\left(A^2_\tau - \mu^2 + m^2_{\tilde\nu} + M^2_{H^\pm}s^2_\beta + M^2_{G^\pm}c^2_\beta\right)\\ &+ \frac{\alpha_\tau}{\varepsilon}\left((m^2_{\tilde\tau_1} - m^2_{\tilde\tau_2})s_{4\tau} + 3m_\tau A_\tau c_{2\tau}\right)\Bigg]\frac{1}{m^2_{\tilde\tau_1} - m^2_{\tilde\tau_2}}.\end{aligned} \tag{A.19}$$

Appendix A.3. *Higgs sector*

In order to obtain renormalization constants for Higgs masses and mixing angles we need to consider divergent parts of self-energy diagrams. The straightforward calculation leads to the following results

$$\begin{aligned}(4\pi)\,\delta m^2_{\Phi_1} &= 3\frac{\alpha_t}{\varepsilon}s^2_\theta\left(m^2_{\tilde t_1} + m^2_{\tilde t_2} - 2m^2_t + m^2_{\Phi_2} + (A_t - \mu\frac{c_\theta}{s_\theta})^2\right)\\ &+ 3\frac{\alpha_b}{\varepsilon}c^2_\theta\left(m^2_{\tilde b_1} + m^2_{\tilde b_2} - 2m^2_b + m^2_{\Phi_2} + (A_b - \mu\frac{s_\theta}{c_\theta})^2\right)\\ &+ \frac{\alpha_\tau}{\varepsilon}c^2_\theta\left(m^2_{\tilde\tau_1} + m^2_{\tilde\tau_2} - 2m^2_\tau + m^2_{\Phi_2} + (A_b - \mu\frac{s_\theta}{c_\theta})^2\right)\end{aligned} \tag{A.20}$$

$$\begin{aligned}(4\pi)\,\delta m^2_{\Phi_2} &= 3\frac{\alpha_t}{\varepsilon}c^2_\theta\left(m^2_{\tilde t_1} + m^2_{\tilde t_2} - 2m^2_t + m^2_{\Phi_1} + (A_t + \mu\frac{s_\theta}{c_\theta})^2\right)\\ &+ 3\frac{\alpha_b}{\varepsilon}s^2_\theta\left(m^2_{\tilde b_1} + m^2_{\tilde b_2} - 2m^2_b + m^2_{\Phi_1} + (A_b + \mu\frac{c_\theta}{s_\theta})^2\right)\\ &+ \frac{\alpha_\tau}{\varepsilon}s^2_\theta\left(m^2_{\tilde\tau_1} + m^2_{\tilde\tau_2} - 2m^2_\tau + m^2_{\Phi_1} + (A_b + \mu\frac{c_\theta}{s_\theta})^2\right)\end{aligned} \tag{A.21}$$

$$
\begin{aligned}
(4\pi)\,\delta\theta = \Bigg[& 3\frac{\alpha_t}{\varepsilon}\left(m_{\tilde{t}_1}^2 + m_{\tilde{t}_2}^2 - 2m_t^2 + (A_t - \mu\frac{c_\theta}{s_\theta})(A_t + \mu\frac{s_\theta}{c_\theta})\right) \\
& - 3\frac{\alpha_b}{\varepsilon}\left(m_{\tilde{b}_1}^2 + m_{\tilde{b}_2}^2 - 2m_b^2 + (A_b - \mu\frac{s_\theta}{c_\theta})(A_b + \mu\frac{c_\theta}{s_\theta})\right) \\
& - \frac{\alpha_\tau}{\varepsilon}\left(m_{\tilde{\tau}_1}^2 + m_{\tilde{\tau}_2}^2 - 2m_\tau^2 + (A_\tau - \mu\frac{s_\theta}{c_\theta})(A_\tau + \mu\frac{c_\theta}{s_\theta})\right) \\
& + \left(3\frac{\alpha_t}{\varepsilon} - 3\frac{\alpha_b}{\varepsilon} - \frac{\alpha_\tau}{\varepsilon}\right)\left(\frac{m_{\Phi_1}^2 + m_{\Phi_2}^2}{2}\right)\Bigg]\frac{c_\theta s_\theta}{m_{\Phi_1}^2 - m_{\Phi_2}^2}. \qquad \text{(A.22)}
\end{aligned}
$$

Here $\Phi_1 = \{G, G^\pm, H\}$, $\Phi_2 = \{A, H^\pm, h\}$, $\theta = \{\beta, \beta, \alpha\}$ correspondingly. It is easy to see that for $\delta\beta$ one obtains different expressions when considers $\mathcal{CP}$-odd $(\delta\beta_0)$ and charged higgses $(\delta\beta_\pm)$. This apparent problem "is solved" if we remember that in the true gauge-less limit $M_{G_0}^2 = M_{G^\pm}^2 = 0$ and $M_A^2 = M_{H^\pm}^2$ so $\delta\beta_0 = \delta\beta_\pm$. However, it is convenient to keep the masses different and instead of renormalization of bare angles β_0 and $\beta_\pm$ use the following explicit counter-terms

$$
\begin{aligned}
\delta\mathcal{L}_{ct}^{\beta} = & -\left(M_{G_0}^2 - M_A^2\right)\delta\beta_0 \times G_0 A_0 \\
& -\left(M_{G^\pm}^2 - M_{H^\pm}^2\right)\delta\beta_\pm \times \left(H^+G^- + G^+H^-\right), \qquad \text{(A.23)}
\end{aligned}
$$

where $\delta\beta_0$ and $\delta\beta_\pm$ are given by (A.22) for $(\Phi_1, \Phi_2) = (G, A_0)$ and $(\Phi_1, \Phi_2) = (G^\pm, H^\pm)$ correspondingly. I would like to mention that it is not the end of the story. For the moment we neglected the contributions due to tadpoles described in Sec. 3.

$$
\begin{aligned}
(4\pi)\,\delta_t m_{\Phi_1}^2 = & -3\frac{\alpha_t}{\varepsilon}s_\theta^2\left[m_{\tilde{t}_1}^2 + m_{\tilde{t}_2}^2 - 2m_t^2 + (A_t - \mu\frac{c_\beta}{s_\beta})(A_t - \mu\frac{c_\theta^2}{s_\theta^2}\frac{s_\beta}{c_\beta})\right] \\
& - 3\frac{\alpha_b}{\varepsilon}c_\theta^2\left[m_{\tilde{b}_1}^2 + m_{\tilde{b}_2}^2 - 2m_b^2 + (A_b - \mu\frac{s_\beta}{c_\beta})(A_b - \mu\frac{s_\theta^2}{c_\theta^2}\frac{c_\beta}{s_\beta})\right] \\
& - \frac{\alpha_\tau}{\varepsilon}c_\theta^2\left[m_{\tilde{\tau}_1}^2 + m_{\tilde{\tau}_2}^2 - 2m_\tau^2 + (A_\tau - \mu\frac{s_\beta}{c_\beta})(A_\tau - \mu\frac{s_\theta^2}{c_\theta^2}\frac{c_\beta}{s_\beta})\right], \qquad \text{(A.24)} \\
(4\pi)\,\delta_t m_{\Phi_2}^2 = & -3\frac{\alpha_t}{\varepsilon}c_\theta^2\left[m_{\tilde{t}_1}^2 + m_{\tilde{t}_2}^2 - 2m_t^2 + (A_t - \mu\frac{c_\beta}{s_\beta})(A_t - \mu\frac{s_\theta^2}{c_\theta^2}\frac{s_\beta}{c_\beta})\right] \\
& - 3\frac{\alpha_b}{\varepsilon}s_\theta^2\left[m_{\tilde{b}_1}^2 + m_{\tilde{b}_2}^2 - 2m_b^2 + (A_b - \mu\frac{s_\beta}{c_\beta})(A_b - \mu\frac{c_\theta^2}{s_\theta^2}\frac{c_\beta}{s_\beta})\right] \\
& - \frac{\alpha_\tau}{\varepsilon}s_\theta^2\left[m_{\tilde{\tau}_1}^2 + m_{\tilde{\tau}_2}^2 - 2m_\tau^2 + (A_\tau - \mu\frac{s_\beta}{c_\beta})(A_\tau - \mu\frac{c_\theta^2}{s_\theta^2}\frac{c_\beta}{s_\beta})\right] \qquad \text{(A.25)}
\end{aligned}
$$

$$
\begin{aligned}
(4\pi)\,\delta_t\theta = -\Bigg[& 3\frac{\alpha_t}{\varepsilon}\left(m^2_{\tilde{t}_1} + m^2_{\tilde{t}_2} - 2m_t^2 + (A_t - \mu\frac{c_\beta}{s_\beta})(A_t + \mu\frac{s_\beta}{c_\beta})\right) \\
& - 3\frac{\alpha_b}{\varepsilon}\left(m^2_{\tilde{b}_1} + m^2_{\tilde{b}_2} - 2m_b^2 + (A_b - \mu\frac{s_\beta}{c_\beta})(A_b + \mu\frac{c_\beta}{s_\beta})\right) \\
& - \frac{\alpha_\tau}{\varepsilon}\left(m^2_{\tilde{\tau}_1} + m^2_{\tilde{\tau}_2} - 2m_\tau^2 + (A_\tau - \mu\frac{s_\beta}{c_\beta})(A_\tau + \mu\frac{c_\beta}{s_\beta})\right)\Bigg]\frac{c_\theta s_\theta}{m^2_{\Phi_1} - m^2_{\Phi_2}}.
\end{aligned}
\tag{A.26}
$$

It is interesting to note that for $\Phi_1 = \{G, G^\pm\}$ and $\Phi_2 = \{A, H^\pm\}$

$$
(4\pi)\ \left(\delta m^2_{\Phi_1} + \delta_t m^2_{\Phi_1}\right) = \left(3\frac{\alpha_t}{\varepsilon}s^2_\beta + 3\frac{\alpha_b}{\varepsilon}c^2_\beta + \frac{\alpha_\tau}{\varepsilon}c^2_\beta\right)m^2_{\Phi_1}, \tag{A.27}
$$

$$
\begin{aligned}
(4\pi)\ \left(\delta m^2_{\Phi_2} + \delta_t m^2_{\Phi_2}\right) &= \left(3\frac{\alpha_t}{\varepsilon}c^2_\beta + 3\frac{\alpha_b}{\varepsilon}s^2_\beta + \frac{\alpha_\tau}{\varepsilon}s^2_\beta\right)m^2_{\Phi_2} \\
&\quad + \frac{\mu}{c_\beta s_\beta}\left(A_\tau\frac{\alpha_\tau}{\varepsilon} + 3A_b\frac{\alpha_b}{\varepsilon} + 3A_t\frac{\alpha_t}{\varepsilon}\right) \\
&= m^2_{\Phi_2}\left[\frac{\delta\mu}{\mu} + \left(\frac{\delta v_2}{v_2} - \frac{\delta v_1}{v_1}\right)\left(s^2_\beta - c^2_\beta\right)\right] + \frac{\mu}{c_\beta s_\beta}\delta B,
\end{aligned}
\tag{A.28}
$$

$$
\begin{aligned}
(4\pi)\ (\delta\beta + \delta_t\beta) &= \left(\frac{3}{2}\frac{\alpha_t}{\varepsilon} - \frac{3}{2}\frac{\alpha_b}{\varepsilon} - \frac{1}{2}\frac{\alpha_\tau}{\varepsilon}\right)\frac{m^2_{\Phi_1} + m^2_{\Phi_2}}{m^2_{\Phi_1} - m^2_{\Phi_2}}c_\beta s_\beta \\
&= -c_\beta s_\beta\,(\delta v_2 - \delta v_1)\,\frac{m^2_{\Phi_1} + m^2_{\Phi_2}}{m^2_{\Phi_1} - m^2_{\Phi_2}},
\end{aligned}
\tag{A.29}
$$

where for $m^2_{\Phi_1} = m^2_{G,G^\pm} = 0$ (true goldstones) and $m^2_{\Phi_2} = m^2_A = m^2_{H^\pm} = m_3^2/(c_\beta s_\beta) \equiv B\mu/(c_\beta s_\beta)$ the result can be cross-checked with the help of one-loop renormalization constants

$$
(4\pi)\delta v_1 = -\frac{3}{2}\frac{\alpha_b}{\varepsilon} - \frac{1}{2}\frac{\alpha_\tau}{\varepsilon}, \qquad (4\pi)\delta v_2 = -\frac{3}{2}\frac{\alpha_t}{\varepsilon}, \tag{A.30}
$$

$$
(4\pi)\delta B = 3A_t\frac{\alpha_t}{\varepsilon} + 3A_b\frac{\alpha_b}{\varepsilon} + A_\tau\frac{\alpha_\tau}{\varepsilon} \tag{A.31}
$$

and relations

$$
\delta\beta = \cos^2\beta\,\delta\tan\beta \qquad \delta m^2_A = \delta\left(\frac{B\mu}{c_\beta s_\beta}\right) \tag{A.32}
$$

Appendix A.4. *Other renormalization constants*

For completeness I present one-loop counter-terms for couplings

$$
(4\pi)\delta Z_{\alpha_s} = (6 - 3C_A)\frac{\alpha_s}{\varepsilon} \tag{A.33}
$$

$$
(4\pi)\delta Z_{\alpha_b} = -4C_F\frac{\alpha_s}{\varepsilon} + 6\frac{\alpha_b}{\varepsilon} + \frac{\alpha_t}{\varepsilon} + \frac{\alpha_\tau}{\varepsilon} \tag{A.34}
$$

$$
(4\pi)\delta Z_{\alpha_b} = -4C_F\frac{\alpha_s}{\varepsilon} + 6\frac{\alpha_t}{\varepsilon} + \frac{\alpha_b}{\varepsilon} \tag{A.35}
$$

$$
(4\pi)\delta Z_{\alpha_\tau} = 3\frac{\alpha_t}{\varepsilon} + 4\frac{\alpha_\tau}{\varepsilon} \tag{A.36}
$$

and for the masses of t-quark m_t and higgsinos m_χ (b-quark and τ-lepton are considered in Sec. 4)

$$(4\pi)\delta Z_{m_t} = -2C_F\frac{\alpha_s}{\varepsilon} + \frac{3}{2}\frac{\alpha_t}{\varepsilon} + \frac{1}{2}\frac{\alpha_b}{\varepsilon}, \tag{A.37}$$

$$(4\pi)\delta Z_{m_\chi} = \frac{3}{2}\left(\frac{\alpha_b}{\varepsilon} + \frac{\alpha_t}{\varepsilon}\right) + \frac{1}{2}\frac{\alpha_\tau}{\varepsilon} \tag{A.38}$$

Clearly, δZ_{m_χ} coincide with the renormalization constant for μ (A.11).
